Joint work with Jean-Paul LAURENT

Introduction

- In credit risk portfolio modelling, **dependence** among default events is a crucial assumption
- We will investigate tranches of **Collateralized Debt Obligation (CDO)**
- Which is the impact of **dependence** on
 - CDO tranche premiums ?
 - Risk measures on the aggregate loss associated with the reference portfolio ?

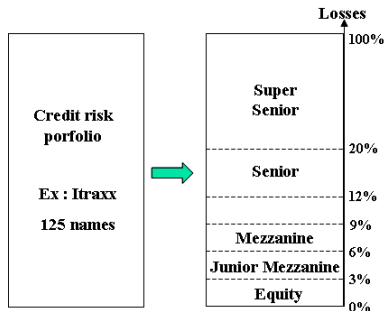

Contents

- 1 CDO tranches
- 2 Comparison results
 - Motivation
 - De Finetti theorem and factor representation
 - Stochastic orders
 - Main results
- 3 Application to several popular CDO pricing models
 - Factor copula approaches
 - Structural model
 - Multivariate Poisson model

CDO tranches

- Slice the credit portfolio into different risk levels or **CDO tranches**
- ex: CDO tranche on **standardized Index** such as CDX North America or Itraxx Europe

- [0, 3%] equity tranche is subordinated to [3, 6%] junior mezzanine tranche
- [3, 6%] junior mezzanine tranche is subordinated to [6, 9%] mezzanine tranche and so on,...

CDO tranches

- Credit portfolio with n reference entities
- τ_1, \dots, τ_n default times
- $(D_1, \dots, D_n) = (1_{\{\tau_1 \leq t\}}, \dots, 1_{\{\tau_n \leq t\}})$ default indicators at time t
- M_1, \dots, M_n losses given default assumed to be independent of default times
- Aggregate loss:

$$L_t = \sum_{i=1}^n M_i 1_{\{\tau_i \leq t\}}$$

- Dynamics of Losses $L_t^{[a,b]}$ affecting CDO tranche $[a, b]$:

CDO tranches

- $L_t^{[a,b]}$ has a call spread payoff with respect to the aggregate loss:

- Loss on CDO tranche $[a, b]$: $L_t^{[a,b]} = (L_t - a)^+ - (L_t - b)^+$
- Computation of CDO Tranche premiums only involves **call options** on the aggregate loss L_t :

$$E [(L_t - a)^+] - E [(L_t - b)^+]$$

- for different time horizons t

Contents

- 1 CDO tranches
- 2 Comparison results**
 - Motivation
 - De Finetti theorem and factor representation
 - Stochastic orders
 - Main results
- 3 Application to several popular CDO pricing models
 - Factor copula approaches
 - Structural model
 - Multivariate Poisson model

Motivation

- Specify the **dependence structure** of default indicators D_1, \dots, D_n which leads to:
 - an increase of the value of **call options** $E[(L_t - a)^+]$ for all strike level $a > 0$
 - an increase of **convex risk measures** on L_t (TVaR, Wang risk measures)
- Comparison between homogeneous credit portfolios
 - D_1, \dots, D_n are assumed to be **exchangeable** Bernoulli random variables
 - De Finetti's theorem leads to a **factor representation** of D_1, \dots, D_n
- Application to several popular CDO pricing models

De Finetti theorem and factor representation

- Homogeneity assumption: default indicators D_1, \dots, D_n forms an exchangeable Bernoulli random vector

Definition (Exchangeability)

A random vector (D_1, \dots, D_n) is exchangeable if its distribution function is invariant for every permutations of its coordinates: $\forall \sigma \in S_n$

$$(D_1, \dots, D_n) \stackrel{d}{=} (D_{\sigma(1)}, \dots, D_{\sigma(n)})$$

- Same marginals

De Finetti theorem and factor representation

- Assume that D_1, \dots, D_n, \dots is an exchangeable sequence of Bernoulli random variables
- Thanks to **de Finetti's theorem**, there exists a random factor \tilde{p} such that
- D_1, \dots, D_n are conditionally independent given \tilde{p}
- Denote by $F_{\tilde{p}}$ the distribution function of \tilde{p} , then:

$$P(D_1 = d_1, \dots, D_n = d_n) = \int_0^1 p^{\sum_i d_i} (1-p)^{n-\sum_i d_i} F_{\tilde{p}}(dp)$$

- Finite exchangeability** only leads to a **sign measure** Jaynes (1986)
- \tilde{p} is characterized by:

$$\frac{1}{n} \sum_{i=1}^n D_i \xrightarrow{a.s.} \tilde{p} \quad \text{as } n \rightarrow \infty$$

- \tilde{p} is exactly the loss of the **infinitely granular portfolio** (Bâle 2 terminology)

Stochastic orders

- The convex order compares the **dispersion level** of two random variables
- **Convex order**: $X \leq_{cx} Y$ if $E[f(X)] \leq E[f(Y)]$ for all convex functions f
- **Stop-loss order**: $X \leq_{sl} Y$ if $E[(X - K)^+] \leq E[(Y - K)^+]$ for all $K \in \mathbb{R}$
 - $X \leq_{sl} Y$ and $E[X] = E[Y] \Leftrightarrow X \leq_{cx} Y$
- $X \leq_{cx} Y$ if $E[X] = E[Y]$ and F_X , the distribution function of X and F_Y , the distribution function of Y are such that:

Supermodular order

- The supermodular order captures the **dependence level** among coordinates of a random vector
- $(X_1, \dots, X_n) \leq_{sm} (Y_1, \dots, Y_n)$ if $E[f(X_1, \dots, X_n)] \leq E[f(Y_1, \dots, Y_n)]$ for all supermodular function f

Definition (Supermodular function)

A function $f : \mathbb{R}^n \rightarrow \mathbb{R}$ is **supermodular** if for all $x \in \mathbb{R}^n$, $1 \leq i < j \leq n$ and $\varepsilon, \delta > 0$ holds

$$\begin{aligned} & f(x_1, \dots, x_i + \varepsilon, \dots, x_j + \delta, \dots, x_n) - f(x_1, \dots, x_i + \varepsilon, \dots, x_j, \dots, x_n) \\ & \geq f(x_1, \dots, x_i, \dots, x_j + \delta, \dots, x_n) - f(x_1, \dots, x_i, \dots, x_j, \dots, x_n) \end{aligned}$$

- Consequences of new defaults are always worse when other defaults have already occurred

Review of literature

Müller(1997)

Stop-loss order for portfolios of dependent risks

$$(D_1, \dots, D_n) \leq_{sm} (D_1^*, \dots, D_n^*) \Rightarrow \sum_{i=1}^n M_i D_i \leq_{sl} \sum_{i=1}^n M_i D_i^*$$

Bäuerle and Müller(2005)

Stochastic orders and risk measures: Consistency and bounds

$$X \leq_{sl} Y \Rightarrow \rho(X) \leq \rho(Y)$$

for all law-invariant, convex risk measures ρ

Lefèvre and Utev(1996)

Comparing sums of exchangeable Bernoulli random variables

$$\tilde{p} \leq_{cx} \tilde{p}^* \Rightarrow \sum_{i=1}^n D_i \leq_{sl} \sum_{i=1}^n D_i^*$$

Main results

- Let us compare two credit portfolios with aggregate loss $L_t = \sum_{i=1}^n M_i D_i$ and $L_t^* = \sum_{i=1}^n M_i D_i^*$
- Let D_1, \dots, D_n be exchangeable Bernoulli random variables associated with the mixture probability \tilde{p}
- Let D_1^*, \dots, D_n^* exchangeable Bernoulli random variables associated with the mixture probability \tilde{p}^*

Theorem

$$\tilde{p} \leq_{cx} \tilde{p}^* \Rightarrow (D_1, \dots, D_n) \leq_{sm} (D_1^*, \dots, D_n^*)$$

- In particular, if $\tilde{p} \leq_{cx} \tilde{p}^*$, then:
 - $E[(L_t - a)^+] \leq E[(L_t^* - a)^+]$ for all $a > 0$.
 - $\rho(L_t) \leq \rho(L_t^*)$ for all convex risk measures ρ

Main results

- Let D_1, \dots, D_n, \dots be exchangeable Bernoulli random variables associated with the mixture probability \tilde{p}
- Let $D_1^*, \dots, D_n^*, \dots$ be exchangeable Bernoulli random variables associated with the mixture probability \tilde{p}^*

Theorem (reverse implication)

$$(D_1, \dots, D_n) \leq_{sm} (D_1^*, \dots, D_n^*), \forall n \in \mathbb{N} \Rightarrow \tilde{p} \leq_{cx} \tilde{p}^*.$$

Contents

- 1 CDO tranches

Ordering of CDO tranche premiums

Burtschell, Gregory, and Laurent(2008)

A comparative analysis of CDO pricing models

- Analysis of the dependence structure within some **factor copula** models such as:
 - Gaussian, Student t , Double t , Clayton, Marshall-Olkin copula
- An **increase** of the dependence parameter leads to:
 - a **decrease** of $[0\%, b]$ **equity tranches** premiums (which guaranties the uniqueness of the market base correlation)
 - an **increase** of $[a, 100\%]$ **senior tranches** premiums

Additive factor copula approaches

- The dependence structure of default times is described by some latent variables V_1, \dots, V_n such that:
 - $V_i = \rho V + \sqrt{1 - \rho^2} \bar{V}_i, i = 1 \dots n$
 - $V, \bar{V}_i, i = 1 \dots n$ independent
 - $\tau_i = G^{-1}(H_\rho(V_i)), i = 1 \dots n$
 - G : distribution function of τ_i
 - H_ρ : distribution function of V_i
- $D_i = 1_{\{\tau_i \leq t\}}, i = 1 \dots n$ are conditionally independent given V
- $\frac{1}{n} \sum_{i=1}^n D_i \xrightarrow{a.s.} E[D_i | V] = P(\tau_i \leq t | V) = \tilde{p}$

Additive factor copula approaches

Theorem

For any fixed time horizon t , denote by $D_i = 1_{\{\tau_i \leq t\}}$, $i = 1 \dots n$ and $D_i^* = 1_{\{\tau_i^* \leq t\}}$, $i = 1 \dots n$ the default indicators corresponding to (resp.) ρ and ρ^* , then:

$$\rho \leq \rho^* \Rightarrow \tilde{\rho} \leq_{cx} \tilde{\rho}^* \Rightarrow (D_1, \dots, D_n) \leq_{sm} (D_1^*, \dots, D_n^*)$$

- This framework includes popular factor copula models:
 - One factor Gaussian copula - the industry standard for the pricing of CDO tranches
 - Double t: [Hull and White\(2004\)](#)
 - NIG, double NIG: [Guegan and Houdain\(2005\)](#), [Kalemanova, Schmid and Werner\(2007\)](#)
 - Double Variance Gamma: [Moosbrucker\(2006\)](#)

Archimedean copula

Schönbucher and Schubert(2001), Gregory and Laurent(2003), Madan *et al.*(2004), Friend and Rogge(2005)

- V is a positive random variable with Laplace transform φ^{-1}
- U_1, \dots, U_n are independent Uniform random variables independent of V
- $V_i = \varphi^{-1} \left(-\frac{\ln U_i}{V} \right)$, $i = 1 \dots n$ (Marshall and Olkin (1988))
 - (V_1, \dots, V_n) follows a φ -archimedean copula
 - $P(V_1 \leq v_1, \dots, V_n \leq v_n) = \varphi^{-1} (\varphi(v_1) + \dots + \varphi(v_n))$
- $\tau_i = G^{-1}(V_i)$
 - G : distribution function of τ_i
- $D_i = 1_{\{\tau_i \leq t\}}$, $i = 1 \dots n$ independent knowing V
- $\frac{1}{n} \sum_{i=1}^n D_i \xrightarrow{a.s.} E[D_i | V] = P(\tau_i \leq t | V)$

Archimedean copula

- Conditional default probability: $\tilde{p} = \exp\{-\varphi(G(t)V)\}$

Copula	Generator φ	Parameter
Clayton	$t^{-\theta} - 1$	$\theta \geq 0$
Gumbel	$(-\ln(t))^\theta$	$\theta \geq 1$
Franck	$-\ln[(1 - e^{-\theta t})/(1 - e^{-\theta})]$	$\theta \in \mathbf{R}^*$

Theorem

$$\theta \leq \theta^* \Rightarrow \tilde{p} \leq_{cx} \tilde{p}^* \Rightarrow (D_1, \dots, D_n) \leq_{sm} (D_1^*, \dots, D_n^*)$$

Archimedean copula

- Clayton copula
- Mixture distributions are ordered with respect to the convex order

Structural model

Hull, Predescu and White(2005)

- Consider n firms
- Let $V_{i,t}$, $i = 1 \dots n$ be their asset dynamics

$$V_{i,t} = \rho V_t + \sqrt{1 - \rho^2} \bar{V}_{i,t}, \quad i = 1 \dots n$$

- V , \bar{V}_i , $i = 1 \dots n$ are independent standard Wiener processes
- Default times as first passage times:

$$\tau_i = \inf\{t \in \mathbf{R}^+ | V_{i,t} \leq f(t)\}, \quad i = 1 \dots n, \quad f : \mathbf{R} \rightarrow \mathbf{R} \text{ continuous}$$

- $D_i = 1_{\{\tau_i \leq T\}}$, $i = 1 \dots n$ are conditionally independent given $\sigma(V_t, t \in [0, T])$

Structural model

Theorem

For any fixed time horizon T , denote by $D_i = 1_{\{\tau_i \leq T\}}$, $i = 1 \dots n$ and $D_i^* = 1_{\{\tau_i^* \leq T\}}$, $i = 1 \dots n$ the default indicators corresponding to (resp.) ρ and ρ^* , then:

$$\rho \leq \rho^* \Rightarrow (D_1, \dots, D_n) \leq_{sm} (D_1^*, \dots, D_n^*)$$

Structural model

- $\frac{1}{n} \sum_{i=1}^n D_i \xrightarrow{a.s.} \tilde{p}$
- $\frac{1}{n} \sum_{i=1}^n D_i^* \xrightarrow{a.s.} \tilde{p}^*$
- Empirically, mixture probabilities are ordered with respect to the convex order:
 $\tilde{p} \leq_{cx} \tilde{p}^*$

Multivariate Poisson model

Duffie(1998), Lindskog and McNeil(2003), Elouerkhaoui(2006)

- \bar{N}_t^i Poisson with parameter $\bar{\lambda}$: idiosyncratic risk
- N_t Poisson with parameter λ : systematic risk
- $(B_j^i)_{i,j}$ Bernoulli random variable with parameter p
- All sources of risk are independent
- $N_t^i = \bar{N}_t^i + \sum_{j=1}^{N_t} B_j^i, i = 1 \dots n$
- $\tau_i = \inf\{t > 0 | N_t^i > 0\}, i = 1 \dots n$

Multivariate Poisson model

- Dependence structure of (τ_1, \dots, τ_n) is the Marshall-Olkin copula
- $\tau_i \sim \text{Exp}(\bar{\lambda} + p\lambda)$
- $D_i = 1_{\{\tau_i \leq t\}}$, $i = 1 \dots n$ are conditionally independent given N_t
- $\frac{1}{n} \sum_{i=1}^n D_i \xrightarrow{a.s.} E[D_i | N_t] = P(\tau_i \leq t | N_t)$
- Conditional default probability:

$$\tilde{p} = 1 - (1 - p)^{N_t} \exp(-\bar{\lambda}t)$$

Multivariate Poisson model

- Comparison of two multivariate Poisson models with parameter sets $(\bar{\lambda}, \lambda, \rho)$ and $(\bar{\lambda}^*, \lambda^*, \rho^*)$
- Supermodular order comparison requires equality of marginals:
 $\bar{\lambda} + \rho\lambda = \bar{\lambda}^* + \rho^*\lambda^*$
- 3 comparison directions:
 - $\rho = \rho^*$: $\bar{\lambda}$ v.s λ
 - $\lambda = \lambda^*$: $\bar{\lambda}$ v.s ρ
 - $\bar{\lambda} = \bar{\lambda}^*$: λ v.s ρ

Multivariate Poisson model

Theorem ($\rho = \rho^*$)

Let parameter sets $(\bar{\lambda}, \lambda, \rho)$ and $(\bar{\lambda}^*, \lambda^*, \rho^*)$ be such that $\bar{\lambda} + \rho\lambda = \bar{\lambda}^* + \rho\lambda^*$, then:

$$\lambda \leq \lambda^*, \bar{\lambda} \geq \bar{\lambda}^* \Rightarrow \tilde{p} \leq_{cx} \tilde{p}^* \Rightarrow (D_1, \dots, D_n) \leq_{sm} (D_1^*, \dots, D_n^*)$$

- Computation of $E[(L_t - a)^+]$:
 - 30 names
 - $M_i = 1, i = 1 \dots n$
- When λ increases, the aggregate loss increases with respect to stop-loss order

Multivariate Poisson model

Theorem ($\lambda = \lambda^*$)

Let parameter sets $(\bar{\lambda}, \lambda, p)$ and $(\bar{\lambda}^*, \lambda^*, p^*)$ be such that $\bar{\lambda} + p\lambda = \bar{\lambda}^* + p^*\lambda$, then:

$$p \leq p^*, \bar{\lambda} \geq \bar{\lambda}^* \Rightarrow \tilde{p} \leq_{cx} \tilde{p}^* \Rightarrow (D_1, \dots, D_n) \leq_{sm} (D_1^*, \dots, D_n^*)$$

- Convex order for mixture probabilities

Multivariate Poisson model

Theorem ($\lambda = \lambda^*$)

Let parameter sets $(\bar{\lambda}, \lambda, p)$ and $(\bar{\lambda}^*, \lambda^*, p^*)$ be such that $\bar{\lambda} + p\lambda = \bar{\lambda}^* + p^*\lambda$, then:

$$p \leq p^*, \bar{\lambda} \geq \bar{\lambda}^* \Rightarrow \tilde{p} \leq_{cx} \tilde{p}^* \Rightarrow (D_1, \dots, D_n) \leq_{sm} (D_1^*, \dots, D_n^*)$$

- Computation of $E[(L_t - K)^+]$:
 - 30 names
 - $M_i = 1, i = 1 \dots n$
- When p increases, the aggregate loss increases with respect to stop-loss order

Multivariate Poisson model

Theorem ($\bar{\lambda} = \bar{\lambda}^*$)

Let parameter sets $(\bar{\lambda}, \lambda, p)$ and $(\bar{\lambda}^*, \lambda^*, p^*)$ be such that $p\lambda = p^*\lambda^*$, then:

$$p \leq p^*, \lambda \geq \lambda^* \Rightarrow \tilde{p} \leq_{cx} \tilde{p}^* \Rightarrow (D_1, \dots, D_n) \leq_{sm} (D_1^*, \dots, D_n^*)$$

- Computation of $E[(L_t - K)^+]$:
 - 30 names
 - $M_i = 1, i = 1 \dots n$
- When p increases, the aggregate loss increases with respect to stop-loss order

Conclusion

- When considering an **exchangeable vector** of default indicators, the **conditional independence assumption** is not restrictive thanks to de Finetti's theorem
- The **mixture probability** (the factor) can be viewed as the loss of an infinitely granular portfolio
- We completely characterize the **supermodular order** between exchangeable default indicator vectors in term of the **convex ordering** of corresponding mixture probabilities
- We show that the mixture probability is the key input to study the impact of dependence on **CDO tranche premiums**
- Comparison analysis can be performed with the same method within a large number of popular CDO pricing models
